# Topological States in Out-of-Equilibrium Allosteric Molecular Assemblies

Jan Kocka

Despite noisiness in the cellular environment, molecular systems show a high degree of robustness. A recent new direction in understanding this apparent paradox is the study of topologically protected states in stochastic systems, which robustly confine the dynamics of the system to a lower-dimensional space [1–3]. However, it is unclear what the minimal biochemical ingredients are for such states to occur. Here, we study topological features in a non-equilibrium, thermodynamically-consistent model of a molecular assembly, made of subunits that undergo futile cycles of conformational change and phosphorylation. When the subunits interact allosterically with each other, we find global, concerted cycles that emerge at the scale of the whole assembly. These involve only a small subset of all possible conformations, analogous to topological edge currents in quantum systems. We map out the kinetics, energetics, and biochemical interactions necessary to obtain distinct classes of topological behaviour. Our results suggest that topological states can provide a minimal description of molecular coordination in protein complexes, such as circadian oscillators (e.g. KaiABC) or polymer assembly and disassembly (e.g. microtubules). More broadly, our results demonstrate that stereotyped dynamics can arise purely from non-equilibrium kinetic effects, without the need for an underlying energy landscape to channel them.

### 1 New Notes

#### 1.1 Questions and things to discuss

- Title! Right now it is very clunky. Should it include "thermodynamically consistent"?
- Conclusion bit! Very much not sure about it as it is is it too short? Should I specifically cite the paper I do there as that really proposes a similar but different model for it, or should I instead highlight the locality difference we add to it? Not sure
- In order to expand the conclusion I need to slightly cut down something.
- Should I reference the figure from the abstract?
- Little Things
  - Should I explicitly list what our futile cycle is? It's a bit long and perhaps obvious but I think
    it's nice to give a concrete, simple thing to visualize.
  - I should probably check that using "artificially" where I do is appropriate.
  - "this robustness"  $\rightarrow$  "biological robustness"?
  - Is "We consider" acceptable language?

#### 1.2 General

- So going for Clocks, timers and cell cycle dynamics topic
- Can I squeeze in "non-Hermitian topology" somewhere (I have some references for it, and it is relevant)?

#### 2 Old Notes

**Format** For POL2025 (the one due on the 6th) it should be 250 words, include references and up to 1 figure.

**Topic** I need to choose one of a list of topics. Perhaps the closest might be: "Biomolecular assemblies and condensates" given that the main model is of an allosteric assembly? Others that may be relevant:

- "Patterns, waves, transport, collective phenomena, and microswimmers" there's collective phenomena! but idk about microswimmers
- "Clocks, timers and cell cycle dynamics" if we lean into KaiABC then maybe
- "Protein structure, dynamics and interactions" cause I guess the polymer as I've been calling it would realistically be a protein?
- "Emerging Areas in the Physics of Life" idk what this is but probably not

#### 2.1 Questions

- Approach to talk about a project that has only just started?
- Should I be talking about allostery or not so much? It seems relevant and as an interesting topic but it's not really a core ingredient in it.
- I'm a bit worried that the only "result" is a bit obvious once you think about it. If we add a penalty for NN having different conformation then of course the ones with all the same conformation will be preferred. Then if all are in conformation 1 (tense) then they are ATP driven to bind ligands so they do so. After that they are by our choice of parameters not favoured to debind hence the only thing they can do is change conformation. The same sort of reasoning then completes the cycle.
- Is an ArXiV citation admissible here?[3]

#### 2.2 Key points to cover

- stochastic systems
- futile cycles
- non-equilibrium dynamics
- allostery
- system features
  - complex high dimensional network, not pen-and-paper tractable
  - locality unlike the previous models, have NNs, can model waves along the polymer
  - discrete configurational space
  - Thermodynamically consistent? idk if this is the right wording

- Search for topological states/patterns in realistic systems (this means starting from the ground up with (non-equilibrium) statphys, LDB, no arbitrary choices) with futile cycles
- the futile cycle is implemented via physical parameters by coupling to two physically reasonable asymmetrical processes
